## ABSTRACT

The Atlantic Forest is one of the richest and most threatened biomes in the world, a fact that configures it as a global *hotspot*. We provide here a list of bird species recorded in the municipality of Barra Mansa (RJ), during ten years of *ad libitum* observations in a fragment of Semideciduous Seasonal Forest, one of the most devastated phytophysiognomies of this biome. We recorded 192 species, of which 107 present some degree of forest dependency, 22 that present migratory activity, 24 that are endemic in the biome or in Brazil and 5 that are relevant to conservation as they are almost threatened or vulnerable at some level (global, national or state). Regarding the trophic guild, there was a predominance of insectivorous ( $n=67$ ) and omnivorous ( $n=58$ ) species, which denotes some environmental quality, but pressured by an imminent anthropization. Given the obtained results, the importance of the analyzed fragment for the maintenance of the local biodiversity becomes evident.

**Keywords:** Atlantic Forest; biodiversity; birds; forest fragmentation; Middle Paraíba region.

## RESUMO

A mata atlântica é um dos biomas mais ricos e ameaçados do mundo, fato que a configura como um *hotspot* global. É fornecida aqui uma lista de espécies de aves registradas no município de Barra Mansa (RJ), durante dez anos de observações *ad libitum* em um fragmento de floresta estacional semidecidual, uma das fitofisionomias mais devastadas desse bioma. Foram registradas 192 espécies, das quais 107 possuem algum grau de dependência florestal, 22 apresentam atividade migratória, 24 são endêmicas para o bioma ou Brasil e cinco são consideradas com relevância para a conservação por estarem quase ameaçadas ou vulneráveis em algum nível (global, nacional ou estadual). Com relação à guilda trófica, houve uma predominância de espécies insetívoras ( $n=67$ ) e onívoras ( $n=58$ ), o que denota uma qualidade ambiental, porém pressionada por uma antropização iminente. Diante dos resultados obtidos, torna-se evidente a importância do fragmento analisado para a manutenção da biodiversidade local encontrada.

**Palavras-chave:** aves; biodiversidade; fragmentação florestal; mata atlântica; região do Médio Paraíba.

## INTRODUCTION

The Atlantic Forest is recognized as one of the biggest *hotspots* in the world, as it harbors a high biodiversity combined with high rates of endemism, and also for its history of constant threats suffered over centuries (TABARELLI et al., 2005; PINTO et al., 2006). Currently, this biome is reduced to only 12.5% of its original distribution, where it is estimated that there are about 891 wild bird species, of which 223 are endemic (MOREIRA-LIMA, 2013; SILVA et al., 2016; VALE et al., 2018).

Among the priority areas for the conservation of the Atlantic Forest, the middle Paraiba river region of the state of Rio de Janeiro (RJ), stands out for presenting one of the most devastated phytophysiognomies of this biome: the Submontane Semideciduous Seasonal Forest (POUGY et al., 2018). This entire area was heavily modified and anthropized, being one of the most deforested during the coffee period in Brazil (DEVIDE, 2013).

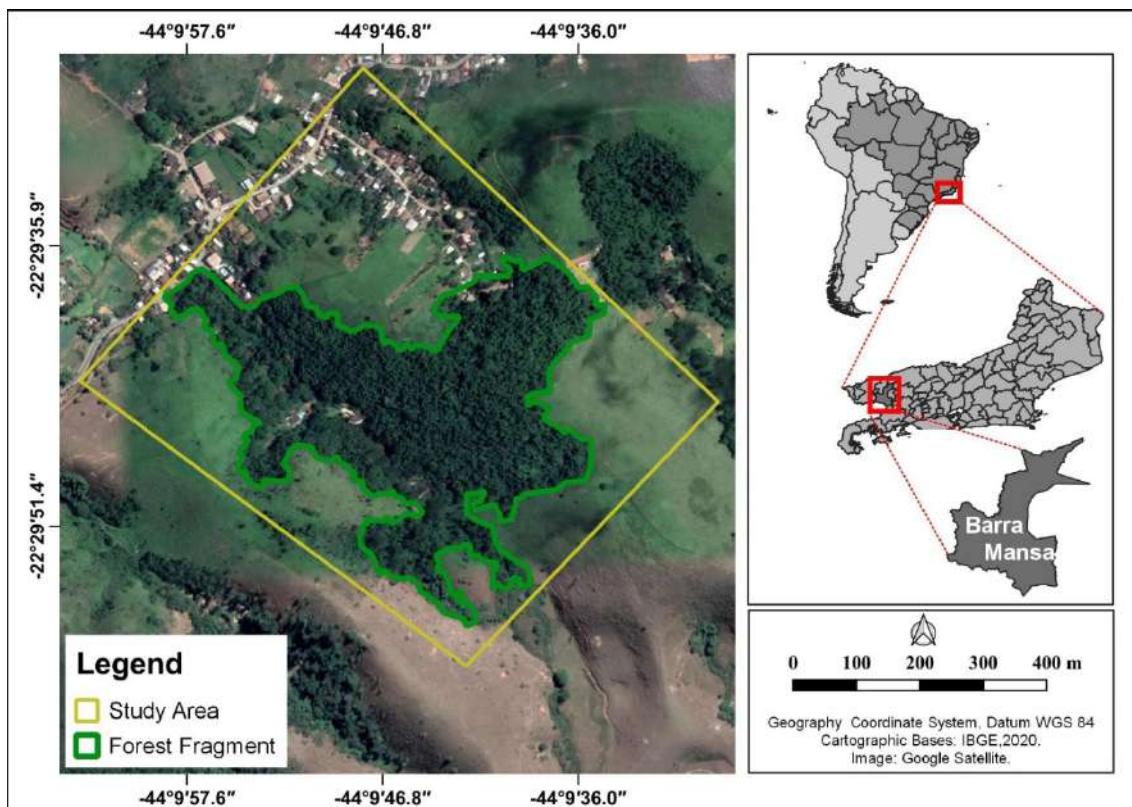

Because birds present varying degrees of ecological demand and respond in different ways to environmental disturbances, these animals are considered excellent bioindicators to attest to the environmental quality of a given location (PIRATELLI et al., 2008). However, knowledge about the bird community that manages to maintain populations in these remaining fragments is still incipient (RIBON et al., 2003). Surveying the extant species is the first step to better understand the processes of extinction and colonization (FARIA et al., 2006).

This work aims to evaluate the richness and composition of bird species found in a fragment of Submontane Semideciduous Seasonal Forest located within some rural properties in the locality of Santa Rita de Cassia, district of Barra Mansa, in the valley of the Paraiba river, in the state of RJ.

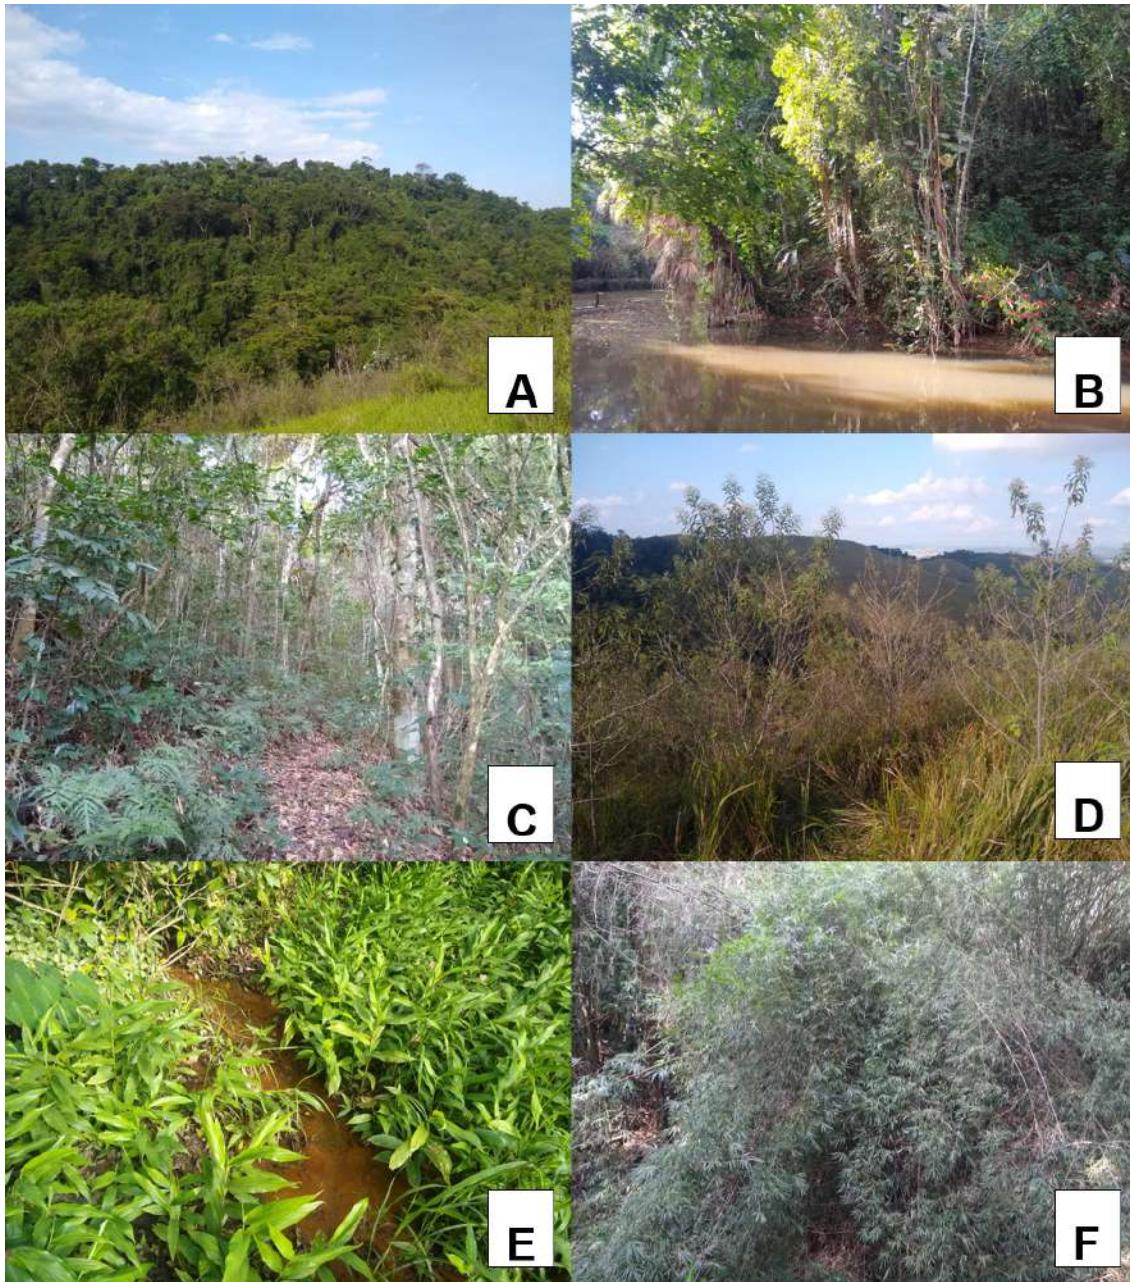

## MATERIAL AND METHODS

This work was carried out in an Atlantic Forest forest remnant of the Submontane Semideciduous Seasonal Forest type (VELOSO et al., 1991), located within the limits of seven private countryside properties (farms and country houses), in the locality of Santa Rita de Cassia, district of the municipality of Barra Mansa, state of RJ (figure 1).

The evaluated forest fragment is a secondary formation, in an advanced stage of regeneration (CONAMA, 1993) and it has a total area of 19.8 hectares. Located at the geographic coordinate 22°29'45.40" S 44°09'48.33" W, its terrain has altitudes ranging from 479 to 576 meters high. In addition to the forest fragment studied, the surroundings were also analyzed, that present a predominant matrix of pastures and shrubby scrub, and represent 62.2 % of the total area assessed (51.1 hectares) (figure 2). It is also worth mentioning that the study fragment is located at a distance of approximately 4.5 km (in a straight line) from the ArcelorMittal plant of the municipality of Barra Mansa, a steel industry; and approximately 5 km away (in a straight line) from the Companhia Siderurgica Nacional (CSN) in the municipality of Volta Redonda, the largest steel industry in Latin America.

**Figure 2** – Some of the different types of environments found in the study area: (A) panoramic view of the Submontane Semideciduous Seasonal Forest fragment; (B) lake; (C) internal view of the forest; (D) formation of shrubby scrub; (E) marsh; (F) bamboo groves. Source: photos by Carlos Nei Ortúzar Ferreira.

Located in the rural area of Barra Mansa city, the village of Santa Rita de Cassia has a strong aptitude for the production of vegetables, in addition to housing many farms that are intended for livestock production (IBGE, 2021) (figure 3).

**Figure 3** – (A) Partial view of Santa Rita de Cassia village; (B) Adjacent lands to the forest fragment with vegetables production and farms. Source: photos by Carlos Nei Ortúzar Ferreira.

*Ad libitum* observations were made over ten years (2011-2021), in the different environments found in the fragment and surroundings. To assist the observations, Bushnell H2O Waterproof 12 x 25 mm 132105C binoculars were used, as well as the *playback* technique that consists of reproducing the song or call of a certain species in order to instigate its response and approximation (VIELLIARD & SILVA, 2010). For the purpose of documenting some records, photos were taken using a Kodak Easyshare max z990 camera model, 30Xis wide angle lens, 12 megapixels, a full hd 1080 recorder; as well as songs sound recordings by using a Motorola Moto G6 XT1925 Smartphone model. All of these documented records were deposited in the database of the digital citizen science platform “Wiki Aves – The Encyclopedia of Birds”.

The conservation statuses of the observed species were categorized into three levels of analytical standardization: at a global level according to the International Union for Conservation of Nature (IUCN, 2021); at a national level according to the Ministry of Environment (ICMBio; MMA, 2018); and at a state level (Rio de Janeiro) following Bergallo *et al.* (2000). The criteria used to assess the categorization of endemism and migratory habits followed the most recent information contained in the scientific literature, with endemism following Moreira-Lima (2013) and Vale *et al.* (2018) and with the migration issue based on Somenzari *et al.* (2018). Criteria such as eating habits and forest dependence were also categorized by using specialized literature (WILLIS, 1979; MOTTA-JÚNIOR, 1990; STOTZ *et al.*, 1996; SICK, 1997; WILMAN *et al.*, 2014). The taxonomic classification follows the Brazilian Committee of Ornithological Records (PACHECO *et al.*, 2021).

## RESULTS AND DISCUSSION

In total, 192 species were registered, distributed in 51 families of 21 different orders. The order Passeriformes presented the greatest diversity of taxa, representing about 58.3 % of the observed species ( $n=112$ ). The most representative families were Tyrannidae ( $n=26$  species) and Thraupidae ( $n=25$ ), respectively. Of the total species, 107 have some degree of forest dependence (55 dependent, 52 semi-dependent), 22 show migratory activity (3 migratory, 19 partially migratory) and 24 are endemic to the Atlantic Forest biome or to Brazil. Five species are considered relevant for conservation because they are nearly threatened or vulnerable at some level (globally, nationally or state). Regarding the trophic guild, there was a predominance of insectivorous ( $n=67$ ) and omnivorous ( $n=58$ ) species (figures 4-8) (table 1).

**Table 1** – List of bird species recorded in Santa Rita de Cassia, Barra Mansa, RJ, Brazil. Legend: Local of Record: OA = Open Areas (pasture); F = Forest Fragments; L = Lakes; FA = Flying over the area; U = Urban Area. Forest dependency: D = Dependent; SD = Semi-dependent; I = Independent. Migratory Status: R = Resident; PM = Partially migratory; MGT = Migratory. Conservation Status: LC = Least Concern; NT = Near Threatened; VU = Vulnerable (GL= Global, NT = National, ST= State). Endemism: AF = Atlantic Forest; BR= Brazil. Trophic guild: CAR = Carnivore; DET = Detritivore; FRU = Frugivore; GRA = Granivore; INS = Insectivorous; NEC = Nectarivorous; ONI = Omnivorous.

Comparing this work with other survey data of bird species in the same region and applying a phytobiognomy analysis (TAVARES, 2019; WIKIAVES, 2021), we can state that the study area presented an expected bird composition, with species that are typical of the Submontane Semideciduous Seasonal Forest. Thus, despite having a small size, being surrounded by pastures and suffering from anthropogenic pressure, the studied forest fragment provides a great ecological service for the maintenance of bird biodiversity in the region.

Wintle et al. (2019) found that small forest patches are of paramount importance for the preservation and maintenance of species, especially in the Atlantic Forest, which is mostly reduced to small isolated forest fragments. Therefore, giving up these small fragments would mean giving up a huge biodiversity confined and restricted to these patches of remaining vegetation. Added to this factor, another alarming reality can be seen: the semideciduous seasonal forest phytobiognomy was one of the most decimated in the entire biome (POUGY et al., 2018). For this reason, the evaluated fragment gains even more importance.

In addition, the obtained results allow us to attest to the existing environmental quality, given the high number of species found with some degree of forest dependence ( $n=107$ ) and of endemic species ( $n=24$ ). Forest dependent species are more demanding in terms of environmental quality and therefore serve as bioindicators (GIMENES & ANJOS, 2003). Endemic species are more affected by habitat fragmentation, because their populations are more restricted and therefore more vulnerable (ALEIXO & VIELLIARD, 1995; ANJOS, 2001; RIBON et al., 2003; SANTOS, 2003).

Regarding the species conservation status, we found three near-threatened and two vulnerable species. *Pilherodius pileatus* (Boddaert, 1783) and *Campephilus robustus* (Lichtenstein, 1818) are nearly threatened in the state of Rio de Janeiro; *Anhinga anhinga* (Linnaeus, 1766) and *Cyanoloxia brissonii* (Lichtenstein, 1823) are vulnerable, also in the state of Rio (BERGALLO et al., 2000); and *Primolius maracana* (Vieillot, 1816) is almost globally threatened (IUCN, 2021).

Birds with some migratory dynamics represented 11.4% (n=22). Of these, *Harpagus diodon* (Temminck, 1823) and *Turdus flavipes* Vieillot, 1818 are fully migratory species and present forest dependence. Furthermore, *Florisuga fusca* (Vieillot, 1817), *Pachyramphus validus* (Lichtenstein, 1823), *Lathrotriccus euleri* (Cabanis, 1868), *Vireo chivi* (Vieillot, 1817) and *Tersina viridis* (Illiger, 1811) are partially migratory species with forest dependence.

All these listed data further reinforce the importance of the evaluated fragment.

The evaluation of the species trophic guild also proved to be an important environmental indicator. There was a predominance of insectivorous species (n=67) followed by omnivore ones (n=58). The predominance of insectivorous species is an already known pattern for tropical regions, both in more anthropogenic areas and in forest areas (SICK, 1997). However, a high number of omnivorous species has been reported in anthropic regions, as omnivory would have a buffering effect against the variation in the availability of food resources in altered environments (TELINO-JÚNIOR et al., 2005; MORANTE FILHO & SILVEIRA, 2012). Thus, the high representation of omnivorous species demonstrates how the surrounding landscape has been directly influencing the richness and the composition of the fragment's avifauna. Of the listed omnivorous species, 44.8% (n=26) are independent of forest fragments.

Finally, it is important to highlight the risks that housing conglomerates bring to the faunal biodiversity of nearby forests, either by the presence of domestic animals that escape into these fragments, scaring away and sometimes preying on wild animals, or by the practice of hunting, which is still deeply rooted in the minds of some people (BARBOSA et al., 2014; FERNANDES-FERREIRA & ALVES, 2014; BUARQUE et al., 2019). During these ten years of sampling, traces of hunters and some traps left in the fragment were observed, most likely to hunt game animals that inhabit the forest fragment, including some bird species such as *Crypturellus tataupa* (Temminck, 1815) and *Penelope obscura* Temminck, 1815. Added to this, along with the observation of several species typical of open areas around the fragment, the presence of synanthropic species reflects an imminent urbanization that pressures the local biodiversity of the analyzed fragment (WOOD et al., 2014).

## ACKNOWLEDGEMENTS

Special thanks to Alda d'Almeida Ferreira, responsible for taking care of the property where part of the analyzed forest fragment is located, and who always made a point of keeping it preserved.
